Prof. Dr.-Ing. Stefan Deßloch AG Heterogene Informationssysteme Geb. 36, Raum 329 Tel. 0631/205 3275 dessloch@informatik.uni-kl.de

Chapter 7 - Web Service Composition and E-Business Collaboration

Motivation

- Complex web services
 - Need to interact with business partners through web services
 - May combine/utilize existing web services
- Web services composition
 - Ability to create new web services out of existing (web service) components
 - Requirements similar to BPM, Workflow Management
 - separate function from composition logic, ...
- Composition can be iterated
 - Composition result is again a web service
 - Can be used as a building block for further composition steps
- ➡ Middleware for web service composition

2

Enterprise Information Systems

Web Services Composition Middleware

- Main elements
 - composition model and language
 - composed WS is expressed by a composition schema (script)
 - development environment
 - graphical end user tools
 - run-time environment
 - composition "engine"
- Composition vs. coordination middleware
 - composition: focus is on implementation of operations in a web service
 - internal, private
 - for automation of the execution of a composite web service
 - coordination: focus is on conversation protocols
 - public, standardized protocols
 - external coordination for verifying compliance

3

Enterprise Information Systems

Web Services vs. WFMS

- Limitations of conventional composition middleware (e.g., WFMS)
 - Significant effort to integrate existing applications
 - application-specific adapters, wrappers
 - no standard model for component description, interoperability
 - Limited success of composition model standardization
 - WfMC standard is not widely implemented
- Opportunities for Web Services
 - Web Services seem to be adequate components
 - well-defined interfaces, described using WSDL
 - standardized invocation (SOAP)
 - Significant efforts in standardizing WS composition languages
 - Reuse of existing WS "infrastructure" (directory, service selection, ...)
 - WS composition tools are less expensive to develop

4

Enterprise Information Systems

Business Processes and Web Services

- Business Process Execution Language for Web Services (BPEL4WS)
 - XML-based language for specifying business process behavior based on web services
 - Describe business processes that both provide and consume web services
 - Steps (activities)
 - Implemented as an interaction with a web service
 - Information flow into/out of the process
 - Externalized as web service
- Complemented by
 - WS Coordination specification
 - Allows to web services involved in a process to share information that "links" them together
 - Shared coordination context
 - WS AtomicTransaction, WS BusinessActivity specifications
 - Allows to monitor the success/failure of each coordinated activity
 - Reliably cancel the business process, involves compensating activities
- Standardization through OASIS

5

Enterprise Information Systems

BPEL4WS

- BPEL can support specification of both, composition schemas and coordination protocols
 - can be used in both composition and coordination middleware
- Two types of processes
 - executable process (-> composition)
 - defines implementation logic for a composite web service
 - portable between BPEL-conformant environments
 - abstract process (-> coordination)
 - service-centric perspective on coordination protocols
 - describe message exchange between partners
- Business process defines
 - potential execution order of operations (web services)
 - data shared between the web services
 - correlation information
 - partners involved in business process and interfaces they need to implement
 - joint exception handling for collection of web services

6

Enterprise Information Systems

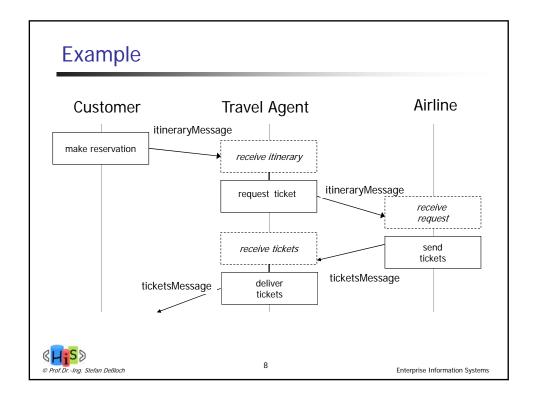

BPEL Component Model

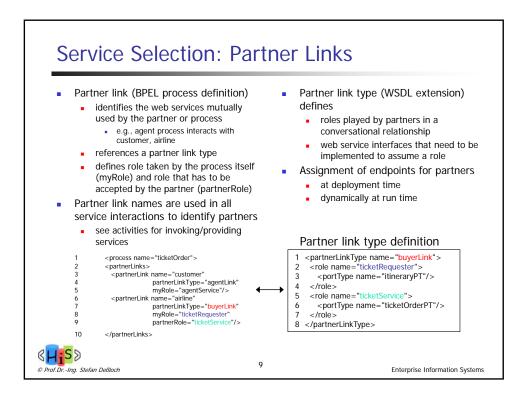

- Components are web services described using WSDL
 - abstract WSDL interfaces are referenced in BPEL scripts
 - no reference to bindings, endpoints, or services
- Basic activities in BPEL represent components, correspond to WSDL operations
 - Invoke
 - Issue an asynchronous request, or
 - Synchronously invoke a request/reply operation of a web service provided by a partner
 - Receive
 - Wait for a message to be received from a partner
 - Specifies partner from which message is to be received, as well as
 - The port and operation provided by the process
 - Used by the partner to pass the message
 - Reply
 - Synchronous response to a request corresponding to a receive activity
 - Combination of Receive/Reply corresponds to request-response operation in WSDL

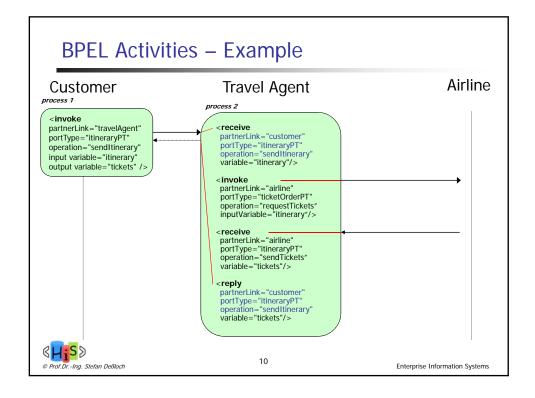

/

Enterprise Information Systems

Orchestration Model - Structured Activities

- Sequence
 - Enclosed activities are carried out in listed order
- If-else (i.e., switch)
 - Selects one of several activities based on selection criteria
- Repetitive Activities
 - While, RepeatUntil,
 - repeatedly carry out enclosed activities while/until specified condition is true
 - ForEach
 - serial: enclosed activity (scope) is carried out repeatedly, based on counter, optional completion condition
 - parallel: (effective copies of) enclosed activity (scope) executed n+1 times in parallel, based on start/end counter values
- Pick
 - Specifies a set of activities with associated events (e.g., receipt of message)
 - messages can be received from the same or different partners
 - activity is completed when one of the events occurs

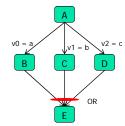

11

Enterprise Information Systems

Structured Activities (cont.)

- Flow activity: defines sets of activities plus (optional) control flow
 - all activities can (potentially) execute in parallel
 - flow activity completes when all directly nested concurrent activities complete
 - implicit fork/join behavior
 - activities can be "wired together" via control links
 - link has one source activity, and one target activity
 - transition conditions
 - evaluated after source activity completes
 - determines the link status to be either true or false
 - links status also set to false, if source activity is determined not to be executed (e.g., if-else)
 - join conditions
 - can refer to status of incoming links of a target activity (e.g., AND, OR)
 - are evaluated only after the status of all incoming links is known
 - false join condition results in a join failure
 - dead path elimination
 - failure may be suppressed, status "false" is propagated to outgoing links

12

Enterprise Information Systems

Process life-cycle

- Start activities
 - receive, pick createInstance attribute
 - creates a new process instance, if it doesn't exist already
 - Example:

```
<receive partner="customer",
    portType="itineraryPT",
    operation="sendItinerary",
    variable="itinerary"
    createInstance="yes"/>
```

- each process must have at least one start activity as an initial activity
- Process termination
 - process-level activity completes successfully
 - fault "arrives" at the process level (handled or not)
 - terminate activity is invoked

13

Enterprise Information Systems

Data Types and Data Transfer

- Variables can be used to define data containers
 - WSDL messages received from or sent to partners
 - Messages that are persisted by the process
 - XML data defining the process state
- Constitute the "business context" of the process
- Access to variables can be serialized to some extent

```
    11 <variables>
    12 <variable name="itinerary" messageType="itineraryMessage"/>
    13 <variable name="tickets" messageType="ticketsMessage"/>
    14 </variables>
```

- Variable assignment
 - Receiving a message (or a reply of an invoke activity) implicitly assigns value
 - Alternative: assign activity (another simple activity)
 - Copies fields from containers into other containers

14

Enterprise Information Systems

Correlation

- Message needs to be delivered not only to the correct port, but to the correct instance of the business process providing the port
 - conversation routing
- Correlation Set
 - one or more properties used for correlating messages
 - example
 - properties="orderNumber"/>
 - </correlationSets>
 - correlation properties are like "late-bound constants"
 - binding happens through specially marked message send/receive activities
 - value must not change after the binding happens
- Often, more than one correlation set is used for an entire process
 - example: orderNumber -> invoiceNumber
 - correlated message exchanges may nest, overlap
 - same message may carry multiple correlation sets

15

Enterprise Information Systems

Properties

- Property
 - Globally defined types
 - Primarily used to correlate a message with a specific process instance
 - E.g., order number
 - Usually included in the message
 - Often the same property is used in different messages
 - Can be defined in BPEL as a separate entity:

```
9 cproperty name="orderNumber" type="xsd:int"/>
```

- Property alias
 - Allows to point to a dedicated field of the message that represents the property
 - Usually different for each message type
 - Can be used in expression and assignments to easily use properties

10 ropertyAlias propertyName="orderNumber" messageType="ticketsMessage" part="orderInfo" query="/orderID"/> 11

- 12
- 13

16

Enterprise Information Systems

WS 2010/2011 8

Scope

- Defines the behavior context of an activity (primary activity)
 - simple or structured (group of activities)
- Can provide the following for a (regular) activity
 - (Local) data variables
 - Correlation Sets
 - Event handler(s)
 - Fault handler(s)
 - Termination handler
 - Compensation handler
 - Scope acts as a compensation sphere
- Scopes can be arbitrarily nested

17

Enterprise Information Systems

Fault Handlers and Termination Handler

- Fault handlers catch and deal with faults occurring in active scope
 - Can catch internal faults (throw activity), WS fault messages
 - All active work in the scope is stopped!
 - Results in invocation of termination handlers for active enclosed scopes
 - After fault handler completes successfully, processing continues outside the scope
 - Processing of the scope is still considered to have ended abnormally
- Termination handler allows to define scope-specific termination behavior
 - Invoked if an active scope needs to be terminated
 - Example: perform cleanup work, notify business partner, cancel activity
 - For nested scope: TH for inner scope is invoked before the TH of the outer

18

Enterprise Information Systems

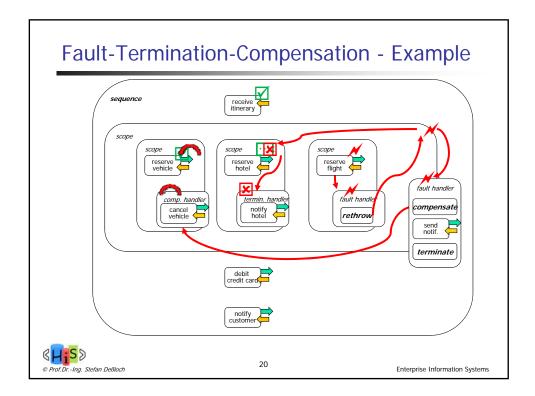

Compensation Handlers

- Compensation handlers reverse the work of a successfully completed scope
 - Compensation handler is "installed" after successful completion of the scope
 - Can be defined for each scope
 - Compensation activity can be any activity
 - Compensation handlers live in a snapshot world
 - When invoked, they see a snapshot of the variables at scope completion time
 - Cannot update "live" data variables
 - Can only affect external entities
 - Input/output parameters for compensation handler are future direction
- Compensate activity
 - Invokes compensation handler for named scope
 - Can be invoked only from the fault handler or compensation handler of the immediately enclosing scope

19

Enterprise Information Systems

Default Compensation and Fault Handlers

- Default compensation handler
 - Invokes compensation handlers of immediately enclosed scopes in the reverse order of the completion of the scopes
 - Is used if a (enclosing) scope does not explicitly define a compensation handler
 - Can also be invoked explicitly
 - Useful if comp. action = "compensate enclosed scope in reverse order" + "additional activities"
- Default fault handler
 - Invokes compensation handlers of immediately enclosed scopes in the reverse order of the completion of the scopes
 - Rethrows the exception

21

Enterprise Information Systems

BPEL – Abstract Processes

- Abstract Process = Role-specific view of a protocol
 - only public information
 - no private, implementation-specific aspects
 - $\, \bullet \,$ branching conditions, activity realization, ...
 - not executable
 - can be used by a conversation controller to ensure business protocol compliance
- Properties of BPEL abstract processes
 - handle only protocol-relevant data
 - message properties
 - variables
 - do not need to be fully initialized
 - variables for inbound or outbound messages may be omitted from invoke, receive, reply, if the intent is to just constrain the sequence of activities
 - opaque assignments
 - can correspond to creating a unique value for correlation properties
 - hide private behavior for providing the values

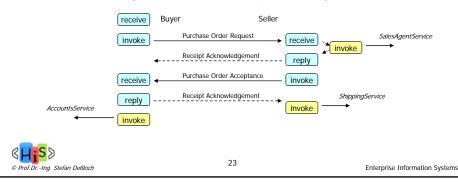

22

Enterprise Information Systems

- Suggested path
 - protocol specification as a starting point
 - derive role-specific views of the protocol
 - includes all the message exchanges that involve a certain role
 - define abstract process for role-specific view
 - model interactions using receive, invoke, reply
 - represent additional public information, such as branching situations, parallelism
 - turn abstract process into an executable process to implement it

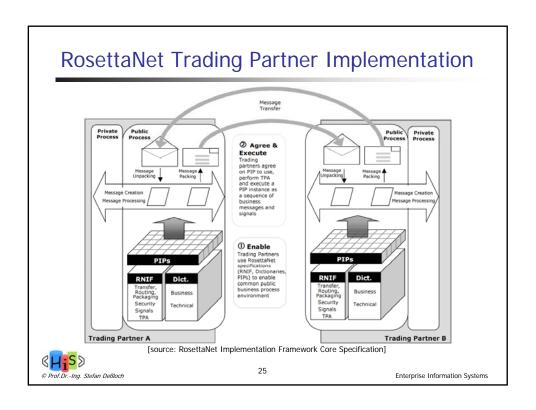

RosettaNet

- Goal: Develop standard e-commerce interfaces to align the processes between IT supply chain partners
 - consortium founded in 1998
 - "vertical" coordination protocols
 - more than 3000 documented production implementations by 2004
- Main standardization areas
 - (Public) Business processes
 - coordination protocols for trading partners
 - Partner Interface Processes (PIPs)
 - business documents, vocabulary, choreography of message exchanges
 - Data format
 - establishment of a common vocabulary
 - business directory
 - technical dictionary
 - Message services
 - RosettaNet Implementation Framework
 reliable, secure execution of the protocol specifications
 - transfer, routing, packaging of encrypted and authenticated messages between business partners

24

Enterprise Information Systems

PIP Definitions

- Standardized PIP definitions are arranged into clusters, further broken down into segments
- Clusters:
 - 1. RosettaNet Support
 - administrative functionality
 - 2. Partner Product and Service Review
 - collect, maintain, distribute product or service information account setup, product info subscription,
 - 3. Product Information
 - distribute, update product information
 query technical product info, ...
 - 4. Order Management request quote, request purchase order, query order status, ...
 - 5. Inventory Management distribute inventory report.
 - 6. Marketing Information Management
 - exchange of marketing information
 - 7. Service and Support
 - 8. Manufacturing
 - "virtual manufacturing"
 - notify of manufacturing work order, ...

26

Enterprise Information Systems

WS 2010/2011 13

Partner Interface Process (PIP) Specifications

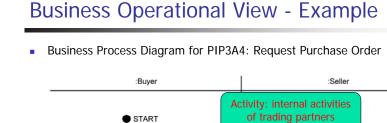

- Describes how to implement a collaborative coordination protocol
 - technical dictionary describes components that are exchanged
 - message guideline document
 - business actions, business signals (ack receipt of action message)
- Major PIP specification sections
 - Business Operational View (aka Action Layer)
 - flow of business interactions, based on
 - partner roles
 - partner role interactions
 - Functional Service View (aka Transaction Layer)
 - derived from the business operational view
 - business transactions between entities in the form of message exchanges
 - ccordination protocols
 - message control information
 - time limits for acknowledgements
 - security requirements
 - Implementation Framework View (aka Service Layer)
 - based on functional service and business operational views
 - defines communication protocol and message format requirements
 - e.g., SSL, encryption, XML DTDs for messages, ...

27

<-RequestConfirmActivity>>
Request Purchase Order

| SUCCESS| | [FAIL] |
| END | FAILED

| Source: PIP3A4 V2.2 specification|

| Document: message exchanges between trading partners

Implementing RosettaNet PIPs

- Involves mapping PIP to WSDL, BPEL
 - types in message definitions -> types in WSDL
 - DTDs to XML Schema
 - message definitions -> WSDL message definitions
 - PIP actions -> operations in WSDL
 - PIP partner roles -> BPEL partners
 - PIP choreography: follow the "suggested path" on previous chart
- Additional aspects
 - realize time-outs, etc. using BPEL events and fault handlers
 - additional requirements regarding security need to be resolved
 - WS-Security support, not integrated in BPEL

31

Enterprise Information Systems

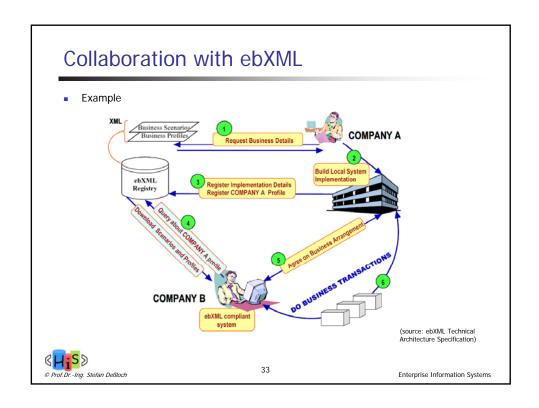

ebXML

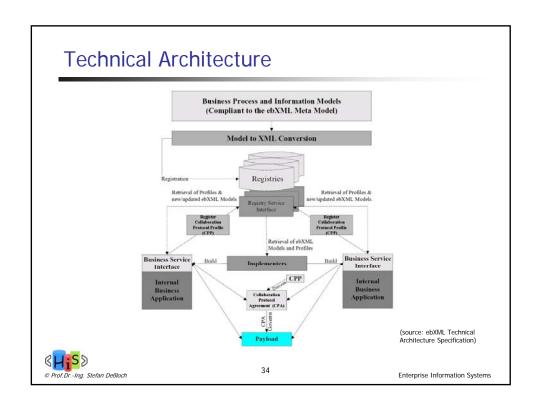

- Supported by UN/CEFACT, OASIS
- Vision
 - single global electronic marketplace
 - based on exchange of XML messages
- ebXML architecture covers:
 - definition of business processes and their associated messages and content
 - registry and discovery of business process sequences with related message exchanges
 - definition of company profiles
 - definition of trading partner agreements
 - uniform message transport layer
- ebXML advantages
 - goes beyond generic protocols and specifications
 - e.g., ebXML registry is much more detailed than UDDI
 - captures the logic behind e-commerce exchanges
 - e.g., business arrangements
 - specifies how e-commerce exchanges should be specified, documented, conducted

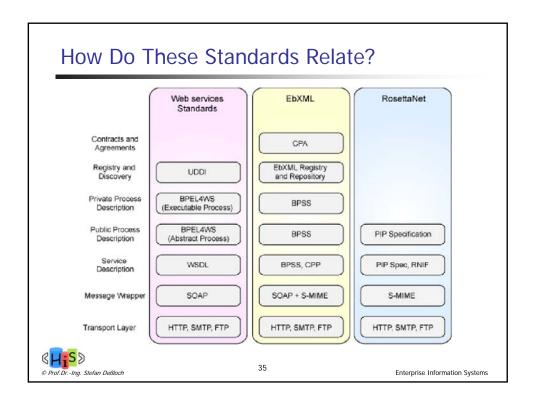

32

Enterprise Information Systems

Summary

- Web service composition
 - means to implement web service by reusing/combining existing services
 - can be supported by WS composition middleware
 - borrowing concepts from WFMS
- BPEL
 - de-facto and de-jure (OASIS) web service composition standard
 - allows definition of composition and coordination aspects
 - abstract vs. executable processes
 - main concepts
 - basic activities for web service operations
 - structured activities for defining service composition, control flow
 - blackboard approach for data flow based on variables
 - service selection based on partner link types, partner links, endpoints
 - elaborate model for transactions and exception handling
 - fault handler, termination handler, compensation handler
- More BPEL extensions are on the way
 - people WF (BPEL4People, WS-HumanTask), Java/SQL snippets (BPELJ, BPEL/SQL)

36

Enterprise Information Systems
